**ABSTRACT**

The inhibition capability of *Triumfetta rhomboidea* (TR) leaves extract on the corrosion of carbon steel in 1 M HCl was evaluated using weight loss technique. Scanning electron microscopy (SEM) analysis was also performed. Results showed that the extract acts as a good inhibitor for carbon steel and its efficiency increases with an increase in its concentration and exposure time. The SEM observations confirmed the existence of a protective film of inhibitor on carbon steel surface. The inhibiting action of *Triumfetta rhomboidea* extract was attributed to the phytochemical species present in the extract and its adsorption on the carbon steel surface. The adsorption of *Triumfetta rhomboidea* extract on carbon steel surface obeys Langmuir adsorption isotherm with physical adsorption on the metal surface.

**Keywords:** *Triumfetta rhomboidea*; carbon steel; weight loss; scanning electron microscopy; adsorption.

1. INTRODUCTION

The use of corrosion inhibitors is one of the most efficient methods of resisting the corrosion of metals from aggressive species. Large numbers of inorganic and organic compounds have been studied to investigate their corrosion inhibition capacity, and they have proven to be good corrosion inhibitors for metals [1-4]. The inhibitory mechanism usually proposed is the adsorption of the inhibitor molecules onto the metal surface, creating a barrier between the metal and the electrolyte, blocking active sites and reducing the metal dissolution and/or reduction reactions [5].

Most synthetic corrosion inhibitors are toxic and pose environmental hazards. Their use, however, has been severely criticised and green corrosion inhibitors are encouraged because they are eco-friendly, non-toxic and inexpensive. Recent researches have shown the corrosion inhibitive effect of some extracts from plants such as Vernonia amygdalina [6], Carica papaya and Camellia sinensis [7], Annona muricata L. [8], Gundelia tournefortii [9], Ocimum sanctum (Holy Basil) [10] and Palicourea guianensis [11]. To mention but a few, exhibiting good inhibitor efficiencies on the corrosion of different metals. The activity of corrosion inhibition of plant extracts could be due to the presence of heterocyclic constituents such as, alkaloids, flavonoids, tannins, cellulose and polycyclic compounds. In this study, the inhibitive properties of Triumfetta rhomboidea leaves extract on the corrosion of carbon steel in 1 M HCl have been investigated using weight loss and scanning electron microscopy (SEM) analysis.

2. MATERIALS AND METHODS

2.1 Material Preparation

Carbon steel material of composition C = 0.015%; Si = 0.027%; Mn = 0.250%; S = 0.027%; P = 0.010%; Ni = 0.014%; Cr = 0.016% and the balance Fe were cut into coupons of dimension 4 cm x 2 cm and used for this study. The coupons were prepared and cleaned as described elsewhere [12]. The blank corrodenet was 1.0 M HCl solution.

The leaves of Triumfetta rhomboidea procured from the herbarium of the Department of Botany, University of Port Harcourt, were crushed into small pieces, dried and powdered. Weighed amount of the powdered materials was refluxed for 1 h using doubled distilled water. After cooling, the solutions were filtered and dried in an oven for one night. Stock solution of the inhibitor was prepared by refluxing weighed amounts of the extract for 3 h in 500 mL of 1 M HCl [13]. The solution was cooled, filtered and stored. From the stock solution, inhibitor test solutions were prepared in concentrations of 50, 100, 150, 200, and 300 ppm in 1 M HCl.

2.2 Weight Loss Measurement

Pre-weighed carbon steel coupons were completely immersed in test solutions containing blank 1 M HCl and various concentration of the inhibitor for 24 hours at 303, 313 and 323K. The weight loss with respect to time was determined by retrieving the coupons from test solutions at the duration of 24 h, cleaned appropriately, dried, and reweighed [14]. The weight loss was taken to be the difference between the weights of the coupons at a given time and its initial weight. The process continued for a period of 120 h. All tests were performed in triplicate to ensure the reproducibility of results, and the mean value of the weight loss reported.

From the weight loss data, the corrosion rate (CR) was determined from the equation below:

\[
CR = \frac{W_1 - W_2}{A \times t}
\]  

(1)

Where \(W_1\) and \(W_2\) are the weights of the metal specimen (mg) before and after immersion in the test solutions, \(A\) is the total area of the specimens (cm\(^2\)) and \(t\) is the immersion time (h).

The surface coverage(\(\theta\)) and inhibition efficiency (%IE) were calculated from the corrosion rate data according to equations 2 and 3, respectively:

\[
\theta = (1 - \frac{CR_{inh}}{CR_{blank}})
\]  

(2)

\[
%IE = (1 - \frac{CR_{inh}}{CR_{blank}}) \times 100
\]  

(3)

Where \(CR_{blank}\) and \(CR_{inh}\) are the corrosion rates in the absence and presence of the inhibitor respectively.

2.3 Scanning Electron Microscopy

The XL-30FEG Scanning Electron Microscope (SEM) was used to picture the changes of the surface morphology of the metal coupons in the
absence and presence of the optimum concentration of *Triumfetta rhomboidea* (TR) leaves extract after immersion in the test solution at 303 K. Carbon steel coupons of dimensions 4 cm × 2 cm were prepared as shown in Section 2.1 and immersed for 24 h in the test solutions, in the absence and presence of 300 ppm TR. The coupons were taken out and washed with distilled water, dried in cool air and used for SEM inspection.

3. RESULTS AND DISCUSSION

3.1 Weight Loss Measurement

The data obtained from the weight loss measurements were: corrosion rate (CR), surface coverage (θ) and inhibition efficiency (%IE). The measurements were obtained at different temperatures of 303, 313 and 323 K and different immersion time of 24, 48, 72, 96 and 120 hours in the presence of 50, 100, 150, 200, and 300 ppm by weight of TR in 1 M HCl.

3.1.1 Effect of concentration

Fig. 1 indicate the variation of corrosion rate for carbon steel with and without different concentrations of the inhibitor in 1 M HCl solution at different temperatures. The figure clearly shows that, corrosion rate decreases significantly as the concentration of the TR increases from 50 ppm to 300 ppm by weight, which indicates the decrease of the carbon steel dissolution in the acidic medium. The decrease in corrosion rate with increase in concentration of TR is due to the fact that the adsorption of inhibitor molecules on the surface of the metal increases the surface coverage of the metal.

The surface coverage and inhibition efficiency calculated for carbon steel from the weight loss study are presented in Table 1. The calculated surface coverage revealed that the increase of the inhibitors concentration from 50 ppm to 300 ppm by weight increased the surface coverage considerably. From the Table, it's also observed that the inhibition efficiency increases with increasing concentration of TR. The maximum inhibition efficiency of 87% was obtained at 300 ppm of TR at 303 K. Similar results for eco-friendly inhibitors have been reported by several researchers [15-18]. From the result obtained it was seen that the inhibitor was very efficient in preventing carbon steel corrosion in 1 M HCl.

3.1.2 Effect of temperature

The effect of temperature on the corrosion inhibition efficiency of *Triumfetta rhomboidea* (TR) in 1M HCl solution was studied by weight loss measurement over temperature range from 303 – 323 K. It is observed from Table 1 that the inhibition efficiency decreases on increasing the temperature of the solution. Increase in the temperature of the solution increases the kinetic energy of the inhibitor and therefore decreases the interaction between the inhibitor and metal surface and thus decreases the inhibition efficiency. Decrease in inhibition efficiency with increase in temperature is suggestive of physical adsorption of TR onto the carbon steel surface [19].

The apparent activation energy $E_a$ for the corrosion of carbon steel samples in 1M HCl solutions in the absence and presence of TR were calculated from Arrhenius-type equation given as:

$$CR = A \exp \left( \frac{-E_a}{RT} \right)$$  \hspace{1cm} (4)

Where $R$ is the gas constant, $A$ is the pre-exponential factor, $T$ is absolute temperature. The values of $E_a$ were determined by plotting $\ln (CR)$ against $1/T$ which gives a straight line with a slope permitting the determination of $E_a$ as shown in Fig. 2. The values of $E_a$ are given in Table 2. The values of $E_a$ for inhibited solution are higher than that for uninhibited solution. The higher value of $E_a$ in presence of TR suggested that there is a reduction in corrosion rate which indicates that more energy barrier is required for the corrosion reaction to occur.

To calculate other activation thermodynamic parameters, an alternative form of Arrhenius equation which is the Eyring’s transition state equation was used (Equ. 5).

$$CR = \left(\frac{RT}{Nh}\right) \exp\left(\frac{\Delta S^*}{R}\right) \exp\left(\frac{\Delta H^*}{RT}\right)$$  \hspace{1cm} (5)

Where $N$ is the Avogadro’s number, $h$ is the Planck's constant, $\Delta S^*$ is the entropy of activation, and $\Delta H^*$ is the enthalpy of activation. A plot of $\log (CR/T)$ vs $1/T$ gave a straight line as shown in Fig. 3 with a slope of $(-\Delta H^*/2.303R)$ and an intercept of $[\log(R/Nh) + (\Delta S^*/R)]$, from which the values of $\Delta H^*$ and $\Delta S^*$ were calculated and listed in Table 2. The positive values of $\Delta H^*$ for corrosion of carbon steel in 1 M HCl in the presence of TR reflect a strong adsorption of the inhibitor on the surface of the metal and it also shows the endothermic nature of metal corrosion process. The negative increment in $\Delta S^*$ with increase in the concentration of the inhibitor reveals that decrease in randomness takes place on going from reactant to the activated complex [20]. This reflects the formation of an ordered stable film of inhibitor on carbon steel surface.

3.2 Scanning Electron Microscopy (SEM) Analysis

The surface morphologies of the carbon steel specimens before immersion and after 24 h of immersion in 1 M HCl blank solutions were studied by SEM examination followed by SEM study after 24 h immersion in 1 M HCl solution containing 300 ppm *Triumfetta rhomboidea* extract. The SEM image of the carbon steel specimen before corrosion in the acidic solution is depicted in Fig. 4 while the corresponding images after 24 h immersion in 1 M HCl without and with *Triumfetta rhomboidea* extract are depicted in Fig. 5. Comparing the SEM images in the absence and presence of *Triumfetta rhomboidea* extract, there was a smoother surface image of the carbon steel in the solution with the inhibitor as compared to without inhibitor. The result clearly shows that the introduction of *Triumfetta rhomboidea* reduced the corrosion of carbon steel by formation of a protective layer on its surface.

3.3 Adsorption Considerations

The effectiveness of organic compounds as corrosion inhibitors can be ascribed to the adsorption of molecules of the inhibitors through their polar functions on the metal surface. Adsorption isotherm values are important to explain the mechanism of corrosion inhibition of organo-electrochemical reactions. The frequently used adsorption isotherm include: Langmuir, Frumkin, Hill de Boer, Parsons, Temkin, Flory-Huggins, among others. Langmuir isotherm was tested for its suitability to the experimental data. Langmuir isotherm is given by the expression:
\[
\frac{C}{\theta} = \frac{1}{K_{ads}} + C
\]  

(6)

Where \(\theta\) is the degree of surface coverage, \(C\) is the inhibitor concentration, \(K_{ads}\) is the equilibrium constant of adsorption process. The plots of \(C/\theta\) against \(C\) are shown in Fig. 6. Linear plots were obtained with good correlation coefficient \((R^2)\) which suggests that adsorption of the inhibitor follow Langmuir adsorption isotherm. Since it obeys Langmuir adsorption isotherm, it implies monolayer adsorption of inhibitor. The adsorption of the inhibitor on the metal surface leads to high degree of surface coverage and hence shows better inhibitive property [21]. The equilibrium constant of adsorption \(K_{ads}\) decreases with increase in temperature (Table 3), indicating that the interactions between the adsorbed molecules and the metal surface are weakened and consequently, the adsorbed molecules could become easily removable. Such data explains the decrease in the inhibition efficiency with increasing temperature [22].

The equilibrium constant of adsorption of *Triumfetta rhomboidea* (TR) extract on the surface of carbon steel is related to the free energy of adsorption \(\Delta G_{ads}\) by Equation 7.

\[
\Delta G_{ads} = -2.303 \frac{RT}{\log (55.5K_{ads})}
\]  

(7)

Where \(R\) is the molar gas constant, \(T\) is the absolute temperature and 55.5 is the concentration of water in solution. The result is presented in Table 3. The negative values of \(\Delta G_{ads}\) suggest that the adsorption of TR extract onto mild steel surface is spontaneous. The values of \(\Delta G_{ads}\) obtained indicate that adsorption of TR extract occurs via physical adsorption mechanism. Generally, values of \(\Delta G_{ads}\) less negative or equal to -20 kJmol\(^{-1}\) (as obtained in this study) are consistent with electrostatic interaction between the charged metals and charged molecules which signifies physical adsorption while values more negative than -40 kJmol\(^{-1}\) signify chemical adsorption [23-27].

4. CONCLUSION

Triumfetta rhomboidea extract acted as an efficient inhibitor for carbon steel in 1M HCl solution. The inhibition efficiency of Triumfetta rhomboidea extract on corrosion of carbon steel in 1 M HCl solution increases on increasing the concentration of Triumfetta rhomboidea extract and decreases with rise in temperature. The increase in activation energies of corrosion process in presence of the extract indicates that Triumfetta rhomboidea extract retards the rate of corrosion of carbon steel in 1 M HCl solution. The nature of adsorption of the extract molecules on carbon steel surface is found to obey Langmuir adsorption isotherm. The phenomenon of physical adsorption is proposed from the obtained thermodynamic parameters. SEM analysis confirms that the inhibition of corrosion of carbon steel is through adsorption of the extract on the surface of the metal.
